AN IMAGE PROCESSING SOFTWARE PACKAGE

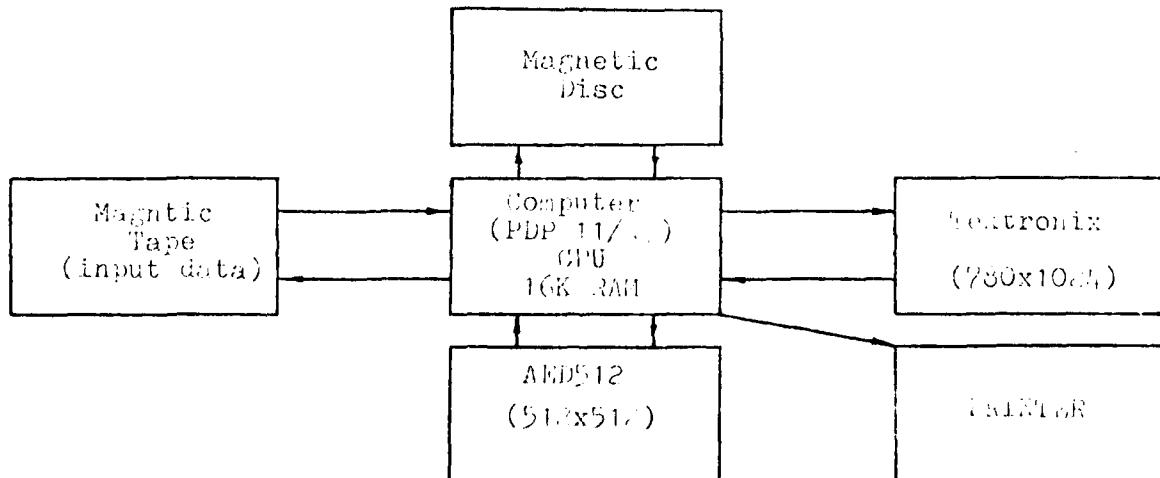

Chihsun, Yen

1. Introduction

Modern technology utilizes all types of pictures, or images, as sources of information for interpretation and analysis. These may be portions of the earth's surface viewed from an orbiting satellite or reconnaissance plane, the inner composition of a complex organic structure seen with the aid of X-rays or microscope. The proliferation of the pictorial data bases has created the need for a vision-based automation that can rapidly, accurately, and cost effectively extract the useful information contained in images. These requirements are being met through the new technology of image processing. The purpose of this report is to introduce the utilities that we have for using image processing and computer results by using some basic image processing functions. A software package is developed and described in detail in the report.

1.1 Utilities

The whole system used to produce the results described herein is shown in the Block Diagram.

A mini-computer (DEC 11/45) with a magnetic disc memory for the storage of pictures receives input data from the magnetic tape. Output data in the form of processed images are stored in the magnetic disc files and displayed on the Tektronix terminal with 2-level or on the AED-12 terminal with the color 16-level or on the printer with 16-level. Control of the image processing functions is made through the Tektronix or AED-12 keyboards. Data and reports are printed on the printer or displayed on the screens.

1.2 Data sources

- The principal image data are provided by
- i Alabama data base (infrared images)
 - ii USC data base
 - iii Reconnaissance images
 - iv Topographic images

1.3 How to used this package?

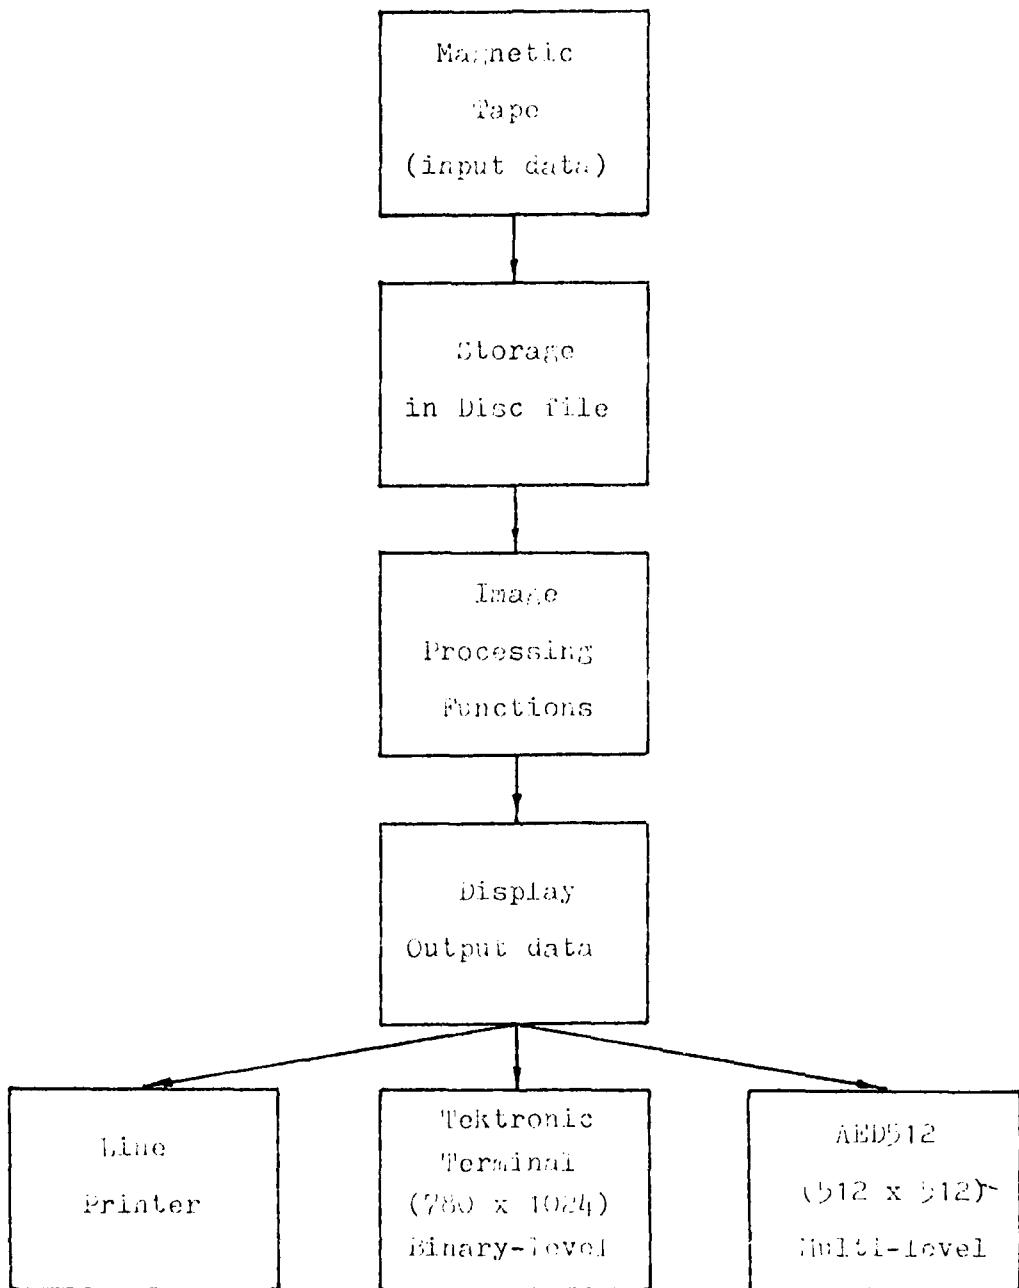

All the program listings are in the Appendix. Next page block diagram is shown how to used this package.

1.4 Some basic image processing functions

a. histogram Equalization (1,2)

For many classes of images, in general, the ideal distribution of gray levels is a uniform distribution. A uniform distribution of gray levels makes equal use of each quantization level and tends to enhance low-contrast information. To use this transformation we may

- i compute the histogram of the image gray level values,

ii add up the histogram values to obtain a distribution curve, $\pi(m)$

iii use this distribution curve for the gray level transformation $G = T(f)$

where G : transferred gray level value

T : transformation symbol

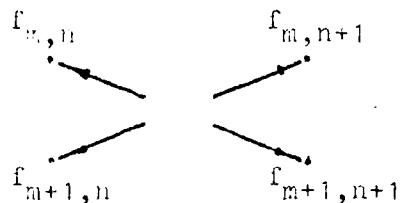

f : original gray level value

b. Robert Gradient Operator (3)

$$d_1 = f_{m,n} - f_{m+1,n+1}$$

$$d_2 = f_{m+1,n} - f_{m,n+1}$$

$$G(m,n) = (d_1^2 + d_2^2)^{\frac{1}{2}}$$

where $f_{m,n}$ is the gray level of point (m,n) ,

$G(m,n)$ is Robert gradient of point (m,n) .

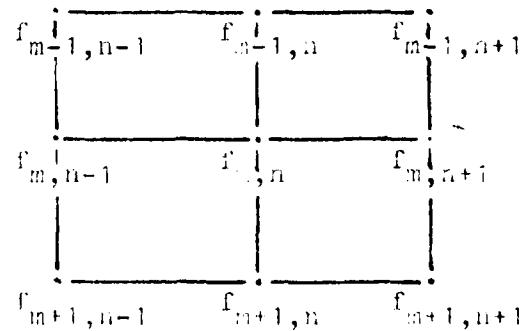

c. Sobel Operator (3)

$$d_X = (f_{m-1,n-1} + 2f_{m,n-1} + f_{m+1,n-1}) - (f_{m-1,n+1} + 2f_{m,n+1} + f_{m+1,n+1})$$

$$d_Y = (f_{m-1,n-1} + 2f_{m-1,n} + f_{m-1,n+1}) - (f_{m+1,n-1} + 2f_{m+1,n} + f_{m+1,n+1})$$

$$S(m,n) = (d_X^2 + d_Y^2)^{\frac{1}{2}}$$

where $S(m,n)$ is Sobel gradient of point (m,n) .

a. Modified gradient (4)

A modification of the conventional gradient operations for the first derivative is called modified gradient. Consider a 16-point array

$$\begin{array}{cccc} A & F & G & D \\ B & P & G & H \\ I & J & K & L \\ M & N & O & P \end{array}$$

The modified gradient is defined as

$$\sqrt[4]{abcd}$$

where

$$a = |F - G| + |J - G|$$

$$b = |A - I| + |M - D|$$

$$c = |B - O| + |I - H|$$

$$d = |C - N| + |E - L|$$

e. Masks (5)

Two-dimensional discrete differentiation can be performed by convolving the original image with the compass gradient masks shown in Fig. A. The compass names indicate the slope direction of maximum response. The gradient image is obtained by taking the magnitude of the output of that mask.

<u>Direction of Gradient</u>	<u>Prewitt Masks</u>	<u>Kirsch Masks</u>	<u>Three-level Simple Masks</u>	<u>Five-level Simple Masks</u>

Fig. A

f. Unsharp masking (2)

$$G(m,n) = f(m,n) - F(m,n)$$

where the function $F(m,n)$ is a local average, for example,

$$F(m,n) = \frac{1}{3} \sum_{i=-1}^1 \sum_{j=-1}^1 f(m+i, n+j), \quad i+j \neq 0$$

g. First order linear model (6)

A first-order autoregressive image model can be written as

$$f(m,n) - \mu_c = \beta_c((f(m-1,n) - \mu_c) + (f(m,n-1) - \mu_c)) + \eta(m,n)$$

$$m = 1, 2, \dots, M$$

$$n = 1, 2, \dots, N$$

where, $\eta(m,n)$ is an uncorrelated Gaussian white noise process, and μ_c is the sample mean. Rearrange the above equation to get

$$f(m,n) = \alpha_c + \beta_c(f(m-1,n) + f(m,n-1)) + \eta(m,n)$$

where,

$$\alpha_c = (1 - 2\beta_c)\mu_c$$

Define

$$G(m,n) = f(m-1,n) + f(m,n-1)$$

Thus

$$f(m,n) = \alpha_c + \beta_c G(m,n) + \eta(m,n)$$

The least mean square estimator (also the maximum likelihood estimator because of Gaussian assumption (6)) is given by

$$\hat{\alpha} = \frac{\sum_m \sum_n G(m,n)f(m,n)}{\sum_m \sum_n (G(m,n))^2}$$

$$\hat{\alpha} = \bar{f} - \bar{G}\bar{f}$$

where

$$F = \frac{\sum_m \sum_n f(m, n)}{MN}$$

$$G = \frac{\sum_m \sum_n g(m, n)}{MN}$$

and

$\hat{b} = \hat{\beta}_c$ = the estimator of β_c

$\hat{a} = \hat{\alpha}_c$ = the estimator of α_c

h. The Kalman filter (?)

The signal model of the Kalman filter is

$$X_{K+1} = F_K X_K + G_K \mathcal{W}_K$$

$$Z_K = Y_K + V_K = H_K^T X_K + V_K$$

where, X_0 , $\{\mathcal{W}_K\}$, and $\{V_K\}$ are jointly Gaussian and mutually independent; X_0 is Gaussian distributed with mean \bar{X}_0 and covariance P_0 respectively; $\{V_K\}$ is zero mean with covariance $R_K \boldsymbol{\delta}_{KK}$; $\{\mathcal{W}_K\}$ is zero mean with covariance $\Omega_K \boldsymbol{\delta}_{KK}$.

The filter equations of the Kalman filter is given by

$$\hat{X}_{K+1/K} = (F_K - K_{K/K} H_K^T) \hat{X}_{K/K-1} + K_{K/K} Z_K$$

$$\hat{X}_{0/K-1} = \hat{X}_0$$

$$K_K = F_K \boldsymbol{\Sigma}_{K/K-1} H_K (H_K^T \boldsymbol{\Sigma}_{K/K-1} H_K + R_K)^{-1}$$

$$\begin{aligned} \boldsymbol{\Sigma}_{K/K-1} &= F_K \{ \boldsymbol{\Sigma}_{K/K-1} - \boldsymbol{\Sigma}_{K/K-1} H_K (H_K^T \boldsymbol{\Sigma}_{K/K-1} H_K + R_K)^{-1} H_K \\ &\quad \boldsymbol{\Sigma}_{K/K-1} \} F_K^T + G_K \Omega_K G_K^T \end{aligned}$$

$$\boldsymbol{\Sigma}_{0/K-1} = P_0$$

$$\hat{x}_{K/K} = \hat{x}_{K/K-1} + \Sigma_{K/K-1} h_K^T (\Sigma_{K/K-1} h_K + R_K)^{-1}$$

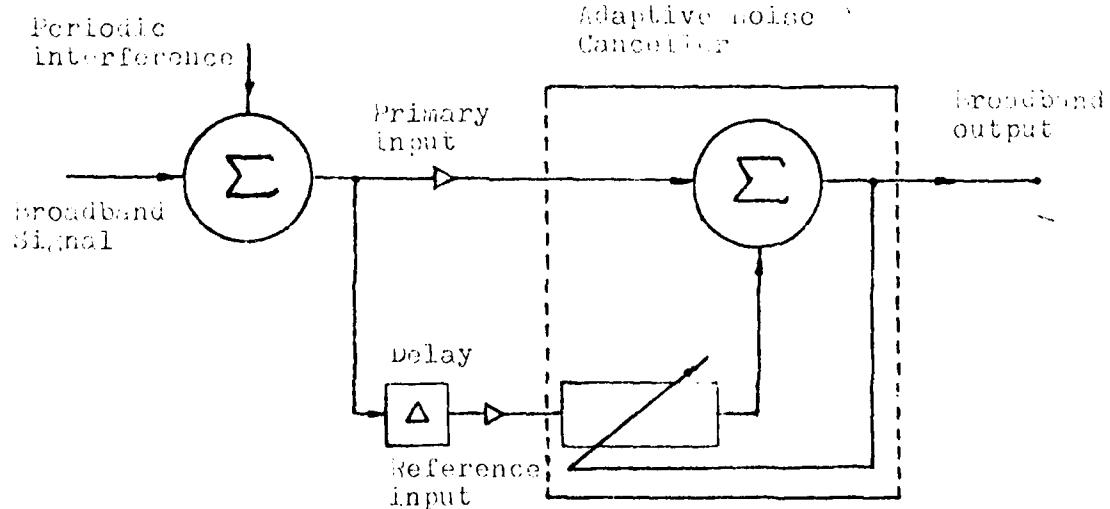

$$(x_K - h_K \hat{x}_{K/K-1})$$

$$\Sigma_{K/K} = \Sigma_{K/K-1} - \Sigma_{K/K-1} h_K^T (\Sigma_{K/K-1} h_K + R_K)^{-1} h_K \Sigma_{K/K-1}$$

The Kalman filter above gives a set of recursive equations for estimating the state of a linear dynamic system. However, the Kalman filter requires a priori knowledge of all the system and noise parameters, which must be identified before using the filter. The following are useful suggestions for implementation:
(Assume K = 1)

- 1. F_K , G_K , and H_K can be set as unity
- 2. If the variance of additive noise is known or can be estimated, then, set the value of R_K to be the variance.
- 3. Ω_K is the system noise, and should be set to a value which is of the order of R; otherwise the filtered results may be undesirable. Usually, $R_K > \Omega_K$.
- i. Adaptive Noise Cancelling Filter (3)

Cancelling periodic interference without an external reference source model is

The input signal vector X_j is defined as

$$X_j \triangleq \begin{bmatrix} x_{0j} \\ x_{1j} \\ \vdots \\ \vdots \\ x_{nj} \end{bmatrix}$$

The weight vector is

$$W = \begin{bmatrix} w_0 \\ w_1 \\ \vdots \\ \vdots \\ w_n \end{bmatrix}$$

where w_0 is the bias weight

The output y_j is

$$y_j = X_j^T W + w_0$$

The error e_j is defined as the difference between the desired response d_j and the actual response y_j .

$$e_j = d_j - y_j = d_j - X_j^T W$$

Expanding the last equation obtains

$$e_j^2 = d_j^2 - 2d_j X_j^T W + W^T X_j X_j^T W$$

Taking the expected value of both sides yields

$$E[e_j^2] = E[d_j^2] - 2E[d_j X_j^T W] + E[W^T X_j X_j^T W]$$

defining the vector r as the cross-correlation between the desired response and X vector then yields

$$r \triangleq E[X_j d_j]$$

The input correlation matrix R is defined as

$$R \triangleq E[X_j X_j^T]$$

The mean-square error can thus be expressed as

$$E[e_j^2] = E[a_j^2] - 2\Gamma^T W + \Gamma^T \Gamma.$$

The gradient ∇ of the error function is obtained by

$$\nabla \frac{\Delta}{2} = -2\Gamma + 2\Gamma W$$

and the gradient estimate is

$$\hat{\nabla}_j = -\epsilon e_j k_j$$

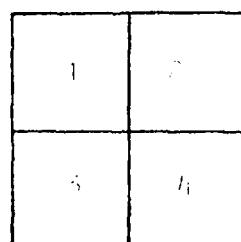

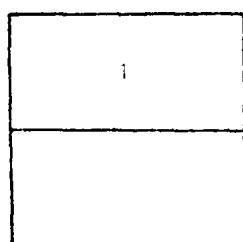

and

$$x_{j+1} = x_j + \mu \epsilon e_j k_j$$

where μ is the factor that controls stability and rate of convergence.

2. Experiments

Currently, we can display binary-level pictures on the Tektronix terminal and 16-level pictures on the AEDB12 terminal. In this report, all the pictures are displayed on the AEDB12 terminal except histogram figures. A reconnaissance image with a tank, a USC image with a cave, and a topographic image with a roadway are being used to demonstrate the capabilities of this package. Table 1 describes the number sequence of sub-pictures of figures 1, 2 & 3.

1	2
3	4
5	6

Table 1

Figure 1a,d is original reconnaissance image with a tank.

Figure 1a.1 is equalized result. The histograms of Figure 1a are shown in the figure 1b. Figure 1c is the results of using Prewitt masks, Kirsch masks, three-level simple masks and five-level simple masks, respectively. The results of using Robert gradient operator, Sobel operator and modified gradient operator are shown in the figure 1d.2,3 & 4, respectively. Figure 1d.1 is original image. Figure 1e is the equalized results of Figure 1d except original image. Figure 1f.3-6 is the computer results of using 1st order ARMA model, Adaptive filter, Kalman filter with horizontal processing, and Kalman filter with vertical processing, respectively. Figure 1f.1 is original image. Figure 1f.2 is additive white Gaussian noise with variance 15 and zero mean. The histograms of Figure 1f are shown in the Figure 1g. The sequence of Figure 2 is same as Figure 1 except that the scene is the topographic image with a roadway and the variance of additive noise is 30. Almost the sequence of Figure 3 is also same as Figure 1 except that the scene is the LSC image with a cave and the Figure 3c is the computer results of using unsharp masking technique.

3. Conclusion Remarks

Currently, we can only display 16-level pictures with any color, for example, figure 2. In the next couple weeks, additional memory planes will be added to the AEDB12 terminal to display all 256 gray levels and the full color pictures. We also plan to add more advanced image processing functions in this package in the near future.

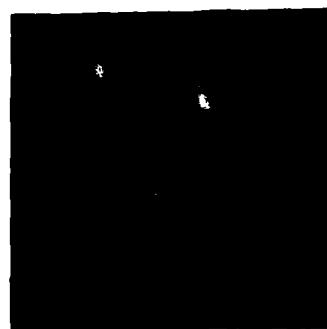

Fig. B

4. Acknowledgments

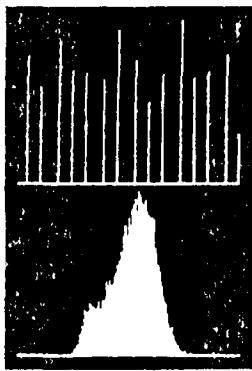

I would like to express my sincere thanks to Professor Peng-Fei Li for his suggestion in the adaptive noise cancelling filter.

Appendix:

A.1 Introduction

The computer programs listed in this appendix were coded in FORTRAN on the TDP-11/45 Minicomputer system monitored under RI-11 operating system.

A.2 Programs

I STORAG.FOR

To store the image from Magnetic tape to disc file.

II FMXMIN.FOR

To find out the maximum and minimum from a file.

III DISPLAY.FOR

To display the image on the AED512 terminal.

IV SETCOL.FOR

For set color table of AED512.

V HISTOG.FOR

To compute the histogram curve of a file and display on the Tektronix terminal.

VI ROBERT.FOR

The Robert gradient operator.

VII SIBEL.FOR

The Sobel operator.

VIII MODGRD.FOR

The modified gradient operator

IX EQ.FOR

The histogram equalization function.

- X PREWIT.FOR
The Prewitt masks.
- XI LOCAL.FOR
The unsharpening masks function.
- XII THSHD.FOR
The simple thresholding function.
- XIII ANOS.FOR
The adding Gaussian noise function.
- XIV ALPHA.FOR
To compute coefficients for 1st order ARMA model.
- XV ARMA.FOR
The 1st order ARMA model
- XVI KALMAN.FOR
The Kalman filter for horizontal processing.
- XVII VR.FOR
The Kalman filter for vertical processing.
- XVIII ADPT.FOR
The adaptive noise cancelling filter.

REPORT DOCUMENTATION PAGE		DATA AS OF DATE OF REPORT	DATA AS OF DATE OF APPROVAL
1. REPORT NUMBER	12. GOVT APPROVAL NO.	13. SEC CLASSIFICATION	14. DATES COVERED
4. TITLE (or SUBTITLE)		An Image Processing Software Package	
5. AUTHOR(S)		Chihsung Yen	
9. PERFORMING ORGANIZATION NAME AND ADDRESS		Electrical Engineering Department Southeastern Massachusetts University North Dartmouth, Mass. 02747	
11. CONTROLLING OFFICE NAME AND ADDRESS		Statistics and Probability Program Office of Naval Research, Code 436 Arlington, Virginia 22217	
14. MONITORING AGENCY NAME & ADDRESS if different from above		15. SECURITY CLASSIFICATION	
16. DISTRIBUTION STATEMENT (of this Report)		Approved for public release, distribution unlimited	
17. DISTRIBUTION STATEMENT (of the abstract entered in Block 2a, if different from above)			
18. SUPPLEMENTARY NOTES			
19. KEY WORDS (Continue on reverse side if necessary and identify by block number)		Image processing functions, software package, multi-level display, reconnaissance images, topographic images, adaptive noise cancelling filter, Kalman filter.	
20. ABSTRACT (Continue on reverse side if necessary and identify by block number)		A software package of major image processing functions is provided with illustrative computer results based on real imagery.
